

MIDGAP DEFECT MODES IN DIELECTRIC AND ACOUSTIC MEDIA*

ALEXANDER FIGOTIN[†] AND ABEL KLEIN[‡]

Abstract. We consider three dimensional lossless periodic dielectric (photonic crystals) and acoustic media having a gap in the spectrum. If such a periodic medium is perturbed by a strong enough defect, defect eigenmodes arise, localized exponentially around the defect, with the corresponding eigenvalues in the gap. We use a modified Birman-Schwinger method to derive equations for these eigenmodes and corresponding eigenvalues in the gap, in terms of the spectral attributes of an auxiliary Hilbert-Schmidt operator. We prove that in three dimensions, under some natural conditions on the periodic background, the number of eigenvalues generated in a gap of the periodic operator is finite, and give an estimate on the number of these midgap eigenvalues. In particular, we show that if the defect is weak there are no midgap eigenvalues.

Key words. photonic crystal, photonic bandgap, periodic acoustic medium, periodic dielectric medium, midgap states, defect modes, localization of light

1. Introduction. Localization of classical waves, acoustic and electromagnetic, has received much attention in recent years (e.g., [An, J1, J2, DE, Sc, VP, M, HJ, JMW] and references therein). This phenomenon arises from coherent multiple scattering and interference and occurs when the scale of the coherent multiple scattering reduces to the wavelength itself. Numerous potential applications (e.g., [DE, J2, VP, HJ]), for instance, the optical transistor, and the fundamental significance of the localization of classical waves motivate the interest in this phenomenon.

In this article we continue our study of localization phenomena due to a single defect in a periodic medium. (A periodic dielectric medium is called a *photonic crystal* (e.g., [JMW])). In a previous article [FK4], we showed that defects do not change the essential spectrum of the associated nonnegative operators. Thus the effect of the defect inside a spectral gap of the periodic medium can only be the creation of isolated eigenvalues of finite multiplicity, with the corresponding eigenmodes decaying exponentially away from the defect. These are usually called *midgap eigenvalues* and *defect eigenmodes*. We also gave a constructive and simple description of defects in acoustic and dielectric media, including a simple condition on the parameters of the

medium and of the defect, which ensures the rise of an defect eigenmode with the corresponding eigenvalue in a specified subinterval of the given gap of the periodic medium.

We have previously given rigorous proofs of Anderson localization due to a random array of defects, both in the lattice [FK1, FK2] and in the continuum [FK3, FK5], including the true three-dimensional continuum case.

We consider acoustic and electromagnetic waves in a lossless, inhomogeneous medium; they are described by the formally self-adjoint operators

$$(1) \quad A = A(\varepsilon) = -\nabla \cdot \frac{1}{\varepsilon(x)} \nabla \quad \text{on } L^2(\mathbb{R}^d),$$

and

$$(2) \quad \mathbf{M} = \mathbf{M}(\varepsilon) = \nabla^\times \frac{1}{\varepsilon(x)} \nabla^\times \quad \text{on } \mathbb{S},$$

where \mathbb{S} , the space of solenoidal fields, is the closure in $L^2(\mathbb{R}^3; \mathbb{C}^3)$ of the linear subset $\{\Psi \in C_0^1(\mathbb{R}^3; \mathbb{C}^3); \nabla \cdot \Psi = 0\}$. We use the notation

$$\nabla^\times \Psi = \nabla \times \Psi = \text{curl } \Psi; \quad \nabla \cdot \Psi = \text{div } \Psi.$$

We also set

$$(3) \quad M = M(\varepsilon) = \nabla^\times \frac{1}{\varepsilon(x)} \nabla^\times \quad \text{on } L^2(\mathbb{R}^3; \mathbb{C}^3).$$

The function $\varepsilon(x)$ describes the medium; it is the position dependent mass density for acoustic waves and the position dependent dielectric constant for electromagnetic waves. We deliberately pick the same notation $\varepsilon(x)$ for the coefficients of the above operators, even so they have different physical meaning, in order to emphasize their similarity and describe uniformly their common spectral properties.

We always assume that $\varepsilon(x)$ is a measurable real-valued function satisfying

$$(4) \quad 0 < \varepsilon_- \leq \varepsilon(x) \leq \varepsilon_+ < \infty \quad \text{a.e. for some constants } \varepsilon_- \text{ and } \varepsilon_+.$$

Localized acoustic or electromagnetic waves are finite energy solutions of the acoustic or Maxwell equations with the property that almost all of the wave's energy remains in a fixed bounded region of space at all times. They can be constructed from exponentially localized eigenmodes (e.g., defect eigenmodes) of the acoustic operator A or the Maxwell operator \mathbf{M} . (See the discussion in [FK3, FK5].)

A *defect* is a perturbation of a given medium in a finite domain. Defects in the medium can generate eigenmodes of A or \mathbf{M} , with corresponding eigenvalues in spectral gaps of the underlying unperturbed medium. This phenomenon is analogous to the rise of bound states for electrons described by Schrödinger operators, due to defects such as a well potential satisfying some simple conditions on its width and depth (e.g., [S]). To employ a mechanism for localization of classical waves similar to the one for electronic localization, we started in [FK4] with a medium described by a coefficient $\varepsilon_0(x)$, such that the corresponding acoustic or Maxwell operator has a gap inside its spectrum with the edges depending on the medium, i.e., on the coefficient $\varepsilon_0(x)$. We proved that if such medium is perturbed locally by a defect (see Fig. 1), the corresponding acoustic or Maxwell operator can exhibit exponentially localized

FIG. 1. A slab of a photonic crystal (a) with an interior defect of higher dielectric constant. The defect is shown on the cross-section of the slab (b) as a darker square.

eigenmodes with corresponding eigenvalues in the interior of the gaps, the *defect eigenmodes*.

The most natural way to obtain media with gaps in the spectrum is to consider periodic media, i.e., media described by periodic $\varepsilon_0(x)$. In this case, the spectra of the corresponding operators A_0 and M_0 , according to Floquet–Bloch theory, have band-gap structure and can have gaps. The existence of gaps for some periodic dielectric and acoustic media was proved in [FKu1, FKU2].

We showed in [FK4] that defects satisfying simple conditions generate defect eigenmodes with corresponding eigenvalues in the gaps, and that the interiors of the gaps contain no points of accumulation of those defect eigenvalues. In this paper, we use a modified Birman–Schwinger method to derive equations for these defect eigenmodes and corresponding midgap eigenvalues, in terms of the spectral attributes of an auxiliary Hilbert–Schmidt operator. We prove that in three-dimensions, under some natural conditions on the periodic background described by $\varepsilon_0(x)$, the number of eigenvalues generated in a gap of the periodic operator is finite, and give an estimate on the number of these midgap eigenvalues. In particular, we show that if the defect is not strong enough no eigenvalues will be generated in the gap, as in the case of three dimensional Schrödinger operators $-\Delta + V$, with V a well potential, where bound states are not created below the continuous spectrum if the well is shallow (e.g., [S]).

2. Statement of results. A and M are defined as the nonnegative self-adjoint operators on $L^2(\mathbb{R}^d)$ and $L^2(\mathbb{R}^3; \mathbb{C}^3)$. They are uniquely defined by the closure of the nonnegative densely defined quadratic forms

$$(5) \quad \mathcal{A}(\psi) = \left\langle \nabla \psi, \frac{1}{\varepsilon(x)} \nabla \psi \right\rangle \equiv \sum_{j=1}^d \left\langle \partial_j \psi, \frac{1}{\varepsilon(x)} \partial_j \psi \right\rangle, \quad \text{with } \psi \in C_0^1(\mathbb{R}^d),$$

and

$$(6) \quad \mathcal{M}(\Psi) = \left\langle \nabla \times \Psi, \frac{1}{\varepsilon(x)} \nabla \times \Psi \right\rangle, \quad \text{with } \Psi \in C_0^1(\mathbb{R}^3; \mathbb{C}^3).$$

We recall Weyl’s decomposition (see [BS]), $L^2(\mathbb{R}^3; \mathbb{C}^3) = \mathbb{S} \oplus \mathbb{G}$, where \mathbb{G} , the space of potential fields, is the closure in $L^2(\mathbb{R}^3; \mathbb{C}^3)$ of the linear subset $\{\Psi \in C_0^1(\mathbb{R}^3; \mathbb{C}^3); \Psi = \nabla\varphi \text{ with } \varphi \in C_0^1(\mathbb{R}^3)\}$. The spaces \mathbb{S} and \mathbb{G} are invariant under M , with $\mathbb{G} \subset \mathcal{D}(M)$ and $M|_{\mathbb{G}} = 0$. We define \mathbf{M} as the restriction of M to \mathbb{S} , i.e., $\mathcal{D}(\mathbf{M}) = \mathcal{D}(M) \cap \mathbb{S}$ and $\mathbf{M} = M|_{\mathcal{D}(M) \cap \mathbb{S}}$. Thus,

$$(7) \quad \mathbf{M} = P_{\mathbb{S}}MI_{\mathbb{S}} = MI_{\mathbb{S}},$$

with $P_{\mathbb{S}}$ the orthogonal projection onto \mathbb{S} and $I_{\mathbb{S}} : \mathbb{S} \rightarrow L^2(\mathbb{R}^3; \mathbb{C}^3)$, the restriction of the identity map. Note $M = \mathbf{M} \oplus 0_{\mathbb{G}}$, so we can work with M to answer questions about the spectrum of \mathbf{M} .

In this article we discuss results common to both acoustic and Maxwell operators. Since most of the discussion will apply to both cases, where it simplifies the discussion we will use W to denote either A or \mathbf{M} , and \widetilde{W} to denote either A or M . We will also write $R(z) = (W - zI)^{-1}$ and $\widetilde{R}(z) = (\widetilde{W} - zI)^{-1}$ for the resolvents. In addition, we will use $\check{R}(z)$ for either $(A - zI)^{-1}$ or $(\mathbf{M} - zI)^{-1} \oplus 0_{\mathbb{G}}$. Note $d = 3$ if $W = \mathbf{M}$.

In this article the *background medium* will be described by a function $\varepsilon_0(x)$ as in (4), which will be taken to be periodic with period q : $\varepsilon_0(x) = \varepsilon_0(x + qm)$ for all $x \in \mathbb{R}^d$ and $m \in \mathbb{Z}^d$. We take $q = 1$ without loss of generality. The corresponding operators will be denoted by $A_0, \mathbf{M}_0, M_0, W_0, \widetilde{W}_0, R_0(z), \widetilde{R}_0(z), \check{R}_0(z)$. An interval (a, b) will be called a *gap* in the spectrum of W_0 , if $a, b \in \sigma(W_0)$ with $a < b$, and $\sigma(W_0) \cap (a, b) = \emptyset$.

We will say that the medium described by $\varepsilon(x)$ (as in (4)) was *obtained from the background medium by the insertion of a defect*, if $\varepsilon(x)$ and $\varepsilon_0(x)$ differ only in a bounded domain, i.e., $\varepsilon(x) - \varepsilon_0(x)$ has compact support; we will then say that $\varepsilon(x)$ and $\varepsilon_0(x)$ *differ by a defect*. In this case the following results are proved in [FK4].

Stability of essential spectrum: W and W_0 have the same essential spectrum, i.e., $\sigma_{\text{ess}}(W) = \sigma_{\text{ess}}(W_0)$. If (a, b) is a gap in the spectrum of W_0 , the spectrum of W in (a, b) consists at most of isolated eigenvalues with finite multiplicity, with the corresponding eigenmodes decaying exponentially fast, with a rate depending on the distance from the eigenvalue to the edges of the gap.

Creation of defect eigenmodes: Let (a, b) be a gap in the spectrum of W_0 , select $\mu \in (a, b)$, and pick $0 < \gamma < 1$ such that the interval $[\mu(1 - \gamma), \mu(1 + \gamma)]$ is contained in the gap, i.e., $[\mu(1 - \gamma), \mu(1 + \gamma)] \subset (a, b)$. If $\varepsilon(x) \equiv \epsilon$ in a cube of side ℓ with

$$(8) \quad \ell^2 \epsilon > \frac{24}{\mu \gamma^2} \left(1 + \sqrt{1 + \frac{d(5 + 2d)}{8} \gamma^2} \right),$$

the corresponding operator W has at least one defect eigenmode, with corresponding eigenvalue inside the interval $[\mu(1 - \gamma), \mu(1 + \gamma)]$.

If either $\varepsilon(x) \geq \varepsilon_0(x)$ or $\varepsilon(x) \leq \varepsilon_0(x)$, we can say more about how the eigenvalues are distributed in the gap. We will call a defect *positive* if $\varepsilon(x) \leq \varepsilon_0(x)$, in which case we have $Y \equiv W - W_0 \geq 0$. Similarly, a defect is *negative* if $\varepsilon(x) \geq \varepsilon_0(x)$, so $Y \leq 0$. We will also write $\widetilde{Y} = \widetilde{W} - \widetilde{W}_0$.

We would like to use the Birman–Schwinger method (e.g., [RS4, Kl, ADH]) to get more information about the eigenvalues a defect creates in a gap, but, unfortunately, $Y = W - W_0$ is not relatively compact with respect to W_0 . The way out is to use the resolvents: we set $H = (W + I)^{-1}$ and $H_0 = (W_0 + I)^{-1}$, prove that $V = H - H_0$ is a Hilbert–Schmidt operator when $d \leq 3$ (see Proposition 5.1), and use the Birman–Schwinger method for $H = H_0 + V$. (A different approach was used in [AADH, BL] to obtain asymptotic results for acoustic operators.)

The Birman–Schwinger method gives equations for the defect eigenmodes and corresponding midgap eigenvalues in terms of the spectral attributes of an auxiliary Hilbert–Schmidt operator. Let (a, b) be a gap in the spectrum of the operator W_0 and let us insert a negative defect, so $\varepsilon(x) \geq \varepsilon_0(x)$ and $V \geq 0$. Let us consider the eigenvalue problem for the operator W in the gap

$$(9) \quad W\psi = \mu\psi, \quad \text{where } \mu \in (a, b).$$

This is clearly equivalent to the eigenvalue problem

$$(10) \quad H\psi = (W + I)^{-1}\psi = (\mu + 1)^{-1}\psi, \quad \text{where } \mu \in (a, b).$$

On the other hand, the eigenvalue problem

$$(11) \quad H\psi = H_0\psi + V\psi = \lambda\psi, \quad \text{where } \lambda \notin \sigma(H_0)$$

can be rewritten as

$$(12) \quad \psi = -R_0(\lambda)V\psi, \quad \text{where } R_0(\lambda) = (H_0 - \lambda I)^{-1}.$$

If we set

$$(13) \quad \mathcal{R}(\lambda) = -\sqrt{V}R_0(\lambda)\sqrt{V},$$

we obtain the eigenvalue problem

$$(14) \quad \mathcal{R}(\lambda)\varphi = \varphi \quad \text{with } \varphi = \sqrt{V}\psi,$$

which is equivalent to the eigenvalue problem (11), as shown in Lemma 4.1. The Birman–Schwinger operator $\mathcal{R}(\lambda)$ is a self-adjoint Hilbert–Schmidt operator (V is Hilbert–Schmidt). The original eigenvalue problem (9) for W can now be rewritten as follows:

$$(15) \quad \mathcal{S}(\mu)\varphi = \varphi, \quad \text{where } \varphi = \sqrt{V}\psi, \quad \mu \in (a, b),$$

and $\mathcal{S}(\mu)$ is the self-adjoint Hilbert–Schmidt operator given by

$$(16) \quad \mathcal{S}(\mu) = \mathcal{R}((\mu + 1)^{-1}) = (\mu + 1)\sqrt{V}\frac{W_0 + I}{W_0 - \mu I}\sqrt{V}.$$

In the case of a positive defect, so $\varepsilon(x) \leq \varepsilon_0(x)$ and $V \leq 0$, the analogue of the equations (15) and (16) takes the form

$$(17) \quad \mathcal{S}(\mu)\varphi = -\varphi, \quad \text{where } \varphi = \sqrt{-V}\psi, \quad \mu \in (a, b),$$

with

$$(18) \quad \mathcal{S}(\mu) = (\mu + 1)\sqrt{-V}\frac{W_0 + I}{W_0 - \mu I}\sqrt{-V}.$$

Observe now that since $(W_0 - \mu I)^{-1}$ is a monotonically increasing, norm-continuous operator function of $\mu \in (a, b)$, the operator $\mathcal{S}(\mu)$ is also a monotonically increasing, norm-continuous function of $\mu \in (a, b)$ for both negative and positive defects. Since

FIG. 2. The equations for the eigenvalues for the defect eigenmodes take the form $\rho_n^+(\mu) = 1$ where the functions $\rho_n^+(\mu)$ are the eigenvalues of an auxiliary compact operator depending on the spectral parameter μ .

$\mathcal{S}(\mu)$ is a self-adjoint Hilbert–Schmidt operator, its spectrum consists of eigenvalues of finite multiplicity with 0 being the only possible point of accumulation. Let $\rho_1^+(\mu) \geq \rho_2^+(\mu) \geq \dots \geq 0$ and $\rho_1^-(\mu) \leq \rho_2^-(\mu) \leq \dots \leq 0$ be the sequences of respectively, the positive and negative eigenvalues of the operator $\mathcal{S}(\mu)$, repeated according to their multiplicity. If we have a finite number of either positive or negative eigenvalues, we complete the sequence by assigning the value 0. The functions $\rho_n^\pm(\mu)$ are monotonically increasing and continuous in $\mu \in (a, b)$.

THEOREM 2.1. *Suppose $d \leq 3$. Let $\varepsilon_0(x)$ be a periodic function satisfying (4), such that the interval (a, b) is a gap in the spectrum of W_0 . Let $\varepsilon(x)$ be obtained from $\varepsilon_0(x)$ by the insertion of a defect. Then:*

(i) *If the defect is negative, the only possible point of accumulation of $\sigma(W) \cap (a, b)$ is b . In this case the eigenvalues $\mu_1 \leq \mu_2 \leq \dots$ of the operator W in the gap (a, b) coincide with the set of the solutions of the equations (see Fig. 2)*

$$(19) \quad \rho_n^+(\mu) = 1, \quad n = 1, 2, \dots,$$

where $\rho_n^+(\mu)$ are the positive eigenvalues of the operator $\mathcal{S}(\mu)$ defined by (16). Moreover, if φ_i is an eigenmode of the operator $\mathcal{S}(\mu_i)$ with eigenvalue $\rho_{n_i}^+(\mu_i) = 1$, then

$$(20) \quad \psi_i = \frac{W_0 + I}{W_0 - \mu_i I} \sqrt{V} \varphi_i$$

is an exponentially localized eigenmode of the operator W with eigenvalue μ_i .

(ii) *If the defect is positive, the only possible point of accumulation of $\sigma(W) \cap (a, b)$ is a . In this case the eigenvalues $\mu_1 \geq \mu_2 \geq \dots$ of the operator W in the gap (a, b) coincide with the set of the solutions of the equations*

$$(21) \quad \rho_n^-(\mu) = -1, \quad n = 1, 2, \dots,$$

where $\rho_n^-(\mu)$ are the negative eigenvalues of the operator $\mathcal{S}(\mu)$ defined by (18). Moreover, if φ_i is an eigenmode of the operator $\mathcal{S}(\mu_i)$ with eigenvalue $\rho_{n_i}^-(\mu_i) = -1$, then

$$(22) \quad \psi_i = -\frac{W_0 + I}{W_0 - \mu_i I} \sqrt{-V} \varphi_i$$

is an exponentially localized eigenmode of the operator W with eigenvalue μ_i .

Note that for defects as in (8) with $\mu = \frac{a+b}{2}$ and $\gamma = \frac{b-a}{a+b}$, defect eigenmodes and midgap eigenvalues always exist (see [FK4, Theorem 2 and Remark 3] for more details), so in this case we can guarantee the existence of a solution for some of equations (19) and (21).

Theorem 2.1 follows from Proposition 5.1 and Theorem 4.4. It reduces the search for defect eigenmodes and midgap eigenvalues of the perturbed operator W to the investigation of the spectral attributes of the relevant Hilbert–Schmidt operator $\mathcal{S}(\mu)$. When it comes to numerical estimations, the reduction to the Hilbert–Schmidt operator $\mathcal{S}(\mu)$ is quite valuable, since clearly $\mathcal{S}(\mu)$ is more suitable for truncations than the original unbounded differential operator W with generally nonsmooth coefficient $\varepsilon(x)$.

In this article, we estimate the number of eigenvalues a defect creates in a gap. To do so, we need a suitable regularity of the resolvent $(W_0 - zI)^{-1}$ in the vicinity of the edges of the spectral gap (a, b) . When $d = 3$ we expect edges to be typically regular. To start with, $\check{R}_0(z)\chi_0$ is a Hilbert–Schmidt operator for any $z \notin \sigma(W_0)$ [FK3, Proposition 42], [FK5, Theorem 18]. Floquet theory [RS4, Ku, FK5] tells us that the spectrum of the periodic operator W_0 is the union of a countable number of bands; more precisely, there exist continuous functions $\{\mu_n(k)\}_{n=1,2,\dots}$ on \mathbb{R}^d (the *dispersion relations*), periodic with period 2π , with $\mu_n(k) \leq \mu_{n+1}(k)$, such that

$$(23) \quad \sigma(W_0) = \bigcup_{n=1,2,\dots} \mu_n(\tilde{Q}), \quad \text{where } \tilde{Q} = [-\pi, \pi)^d.$$

It follows from (4) and the min-max principle that for any closed finite interval $I \subset \mathbb{R}$, we have $\mu_n(\tilde{Q}) \cap I = \emptyset$ except for at most finitely many n 's. Thus, if (a, b) is a gap in the spectrum of W_0 , and $\{\mu_n(k)\}_{n=1,2,\dots}$ are the corresponding dispersion relations, there must exist $n_0 \in \mathbb{N}$ such that $\mu_n(\tilde{Q}) \subset [0, a]$ for all $n \leq n_0$ and $\mu_n(\tilde{Q}) \subset [b, \infty)$ for all $n > n_0$. In addition, there exist a positive integer $n_1 \leq n_0$ such that $a \notin \mu_n(\tilde{Q})$ for either $n < n_1$ or $n > n_0$, and $a = \max \mu_n(\tilde{Q})$ for $n_1 \leq n \leq n_0$. It follows that there exists a constant $c_1 > 0$ such that, if $n < n_1$ or $n > n_0$ we have $|a - \mu_n(k)| \geq c_1 > 0$ for all $k \in \tilde{Q}$.

A natural regularity condition for the left edge a is a *nondegeneracy condition*: for each $n_1 \leq n \leq n_0$ we have $a = \mu_n(k)$ for only finitely many $k \in \tilde{Q}$, say $k_{n,1}, \dots, k_{n,s_n}$, and for any $i = 1, \dots, s_n$ we have

$$(24) \quad a - \mu_n(k) \geq c_i |k - k_{n,i}|^2 \quad \text{for } |k - k_{n,i}| \text{ small, with } c_i > 0,$$

(with a similar definition for the right edge b).

This nondegeneracy condition is a common assumption in the physical literature (e.g., [HJ, Equation (4.53)]). It was also used in the study of Lipschitz tails in spectral gaps of periodic Schrödinger operators [Kp].

Verification of the regularity of a gap edge is not a simple matter even for Schrödinger operators. Below we give two rather natural definitions of regularity

of a gap edge, sufficient for our purposes. Conditions under which one can guarantee the desired regularity is a subject for a separate investigation.

DEFINITION 2.2. *Let (a, b) be a gap in the spectrum of W_0 , let $\{\mu_n\}_{n=1,2,\dots}$ be the corresponding dispersion relations, and let c denote either the left edge a or the right edge b . We say that the edge c is strongly regular if*

$$(25) \quad \int_{\tilde{Q}} \frac{dk}{|\mu_n(k) - c|} < \infty$$

for all $n = 1, 2, \dots$

Note that in three dimensions strong regularity of an edge is an immediate consequence of the nondegeneracy condition.

For our purposes a weaker definition suffices.

DEFINITION 2.3. *We say that the left edge a of the gap (a, b) in the spectrum of the periodic operator W_0 is regular if*

$$(26) \quad \xi(a) \equiv \limsup_{\eta \downarrow 0} \text{Tr} \left[\left(\chi_0 \left| \check{R}_0(a + \eta) \right| \chi_0 \right)^2 \right] < \infty,$$

where χ_0 denotes the characteristic function of the cube of side 1 (i.e., the period of $\varepsilon_0(x)$) centered at the origin. Similarly, the right edge b is regular if

$$(27) \quad \xi(b) \equiv \limsup_{\eta \downarrow 0} \text{Tr} \left[\left(\chi_0 \left| \check{R}_0(b - \eta) \right| \chi_0 \right)^2 \right] < \infty.$$

To put the definition in perspective, note that for z real and not in the spectrum of W_0 , we always have $\text{Tr}[(\chi_0 | \check{R}_0(z) | \chi_0)^2] < \infty$, since

$$(28) \quad \begin{aligned} \text{Tr} \left[\left(\chi_0 \left| \check{R}_0(z) \right| \chi_0 \right)^2 \right] &= \left\| \chi_0 \left| \check{R}_0(z) \right| \chi_0 \right\|_2^2 \\ &\leq \left\| \check{R}_0(z) \left| \chi_0 \right. \right\|_2^2 = \left\| \check{R}_0(z) \chi_0 \right\|_2^2 < \infty, \end{aligned}$$

as $\check{R}_0(z) \chi_0$ is Hilbert–Schmidt by [FK3, Proposition 42], [FK5, Theorem 18], plus the resolvent identity. Furthermore, regularity follows from nondegeneracy; in fact it already follows from strong regularity.

THEOREM 2.4. *When $d = 3$, a strongly regular edge is always regular.*

To formulate our main result we need a definition. For a given a self-adjoint operator H and interval (α, β) , we define

$$(29) \quad N_H(\alpha, \beta) = \text{Tr} \chi_{(\alpha, \beta)}(H).$$

Note $N_H(\alpha, \beta)$ is always a nonnegative integer unless it is infinite. If H has discrete spectrum in (α, β) , $N_H(\alpha, \beta)$ gives the number of eigenvalues of H in (α, β) , counted according to their multiplicity.

It will be convenient to write

$$(30) \quad \varepsilon(x) = \frac{\varepsilon_0(x)}{1 + \theta(x)},$$

where $\theta(x)$ is a bounded measurable function with compact support satisfying

$$(31) \quad -1 < \theta_- \leq \theta(x) \leq \theta_+ < \infty \quad \text{a.e. for some constants } \theta_- \text{ and } \theta_+.$$

In this case we will always take

$$(32) \quad \varepsilon_+ = \frac{\varepsilon_{0,+}}{1 + \theta_-} \quad \text{and} \quad \varepsilon_- = \frac{\varepsilon_{0,-}}{1 + \theta_+}.$$

Note that a defect is *positive* if $\theta(x) \geq 0$, in which case we have $\theta_- = 0$. Similarly, a defect is *negative* if $\theta(x) \leq 0$, so $\theta_+ = 0$.

Our main result is given in the following theorem.

THEOREM 2.5. *Suppose $d = 3$. Let $\varepsilon_0(x)$ be a periodic function satisfying (4), with the interval (a, b) a gap in the spectrum of W_0 . Let us insert a defect by taking $\varepsilon(x)$ be as in (30), where $\theta(x)$ satisfies (31) and vanishes outside a cube Λ_ℓ of side $\ell > 0$. Letting $0 < \delta \leq 1$, we have:*

(i) *Suppose the left edge a is regular and the defect is positive, then*

$$(33) \quad N_W(a, b) \leq C_{a, \varepsilon_0, \pm, \theta_+, \delta} \theta_+^2 (\ell + 3)^{9+\delta} \xi(a) < \infty,$$

with

$$(34) \quad C_{a, \varepsilon_0, \pm, \theta_+, \delta} = \frac{C(a+1)^2}{\delta} \left[1 + \varepsilon_-^{-(6+\delta)} \right] \left[1 + 6 \frac{\sqrt{\varepsilon_{0,+}}}{\varepsilon_{0,-}} \left(\sqrt{\varepsilon_-} + \frac{1}{\sqrt{\varepsilon_-}} \right) \right]^2,$$

where C is some constant, independent of δ and of the other parameters, and $\varepsilon_- = \frac{\varepsilon_{0,-}}{1 + \theta_+}$.

(ii) *Suppose the right edge b is regular and the defect is negative, then*

$$(35) \quad N_W(a, b) \leq C_{b, \varepsilon_0, \pm, \theta_-, \delta} \theta_-^2 (\ell + 3)^{9+\delta} \xi(b) < \infty,$$

with

$$(36) \quad C_{b, \varepsilon_0, \pm, \theta_-, \delta} = \frac{C(b+1)^2}{\delta} \left[1 + \varepsilon_{0,-}^{-(6+\delta)} \right] \left[1 + 6 \frac{\sqrt{\varepsilon_+}}{\varepsilon_{0,-}} \left(\sqrt{\varepsilon_{0,-}} + \frac{1}{\sqrt{\varepsilon_{0,-}}} \right) \right]^2,$$

where C is some constant, independent δ and of the other parameters, and $\varepsilon_+ = \frac{\varepsilon_{0,+}}{1 + \theta_-}$.

Since the function $N_W(a, b)$ is integer valued, $N_W(a, b) < 1$ implies $N_W(a, b) = 0$. Thus we have the following immediate corollary, which tells us that there are no midgap eigenvalues if the defect is small.

COROLLARY 2.6. *Suppose $d = 3$. Let $\varepsilon_0(x)$ be a periodic function satisfying (4), with the interval (a, b) a gap in the spectrum of W_0 . Let us insert a defect by taking $\varepsilon(x)$ be as in (30), where $\theta(x)$ satisfies (31) and vanishes outside a cube Λ_ℓ of side $\ell > 0$. Then:*

(i) *If the left edge a is regular and the defect is positive, we must have $N_W(a, b) = 0$ for $\theta_+ > 0$ small, how small depending only on $a, \varepsilon_{0,\pm}$ and ℓ . In other words, there are no eigenvalues in the gap for weak defects.*

(ii) *If the right edge b is regular and the defect is negative, we must have $N_W(a, b) = 0$ for $\theta_- < 0$ small, how small depending only on $b, \varepsilon_{0,\pm}$ and ℓ , so there are no eigenvalues in the gap for weak defects.*

For the reader's convenience we list some notations used throughout the paper:

- W denotes either A or \mathbf{M} , and \widetilde{W} denotes either A or M . The corresponding acoustic or dielectric medium is described by $\varepsilon(x)$.
- $R(z) = (W - zI)^{-1}$, $\widetilde{R}(z) = (\widetilde{W} - zI)^{-1}$.
- $\check{R}(z)$ denotes either $(A - zI)^{-1}$ or $(\mathbf{M} - zI)^{-1} \oplus 0_{\mathbb{G}}$.

- $A_0, \mathbf{M}_0, M_0, W_0, \widetilde{W}_0, R_0(z), \widetilde{R}_0(z), \check{R}_0(z)$ correspond to the acoustic or dielectric medium described by $\varepsilon_0(x)$.
- $Y = W - W_0, \widetilde{Y} = \widetilde{W} - \widetilde{W}_0$.
- $\#S$ is the number of elements in the set S .
- χ_S is the characteristic function of the set S .
- A bounded operator T , from a Hilbert space \mathcal{H}_1 to another Hilbert space \mathcal{H}_2 , is of class \mathcal{T}_p , where $1 \leq p < \infty$, if $\|T\|_p \equiv [\text{Tr}(T^*T)^{p/2}]^{1/p} < \infty$. In this case we will write $T \in \mathcal{T}_p$. Recall that T is a Hilbert–Schmidt operator if and only if $T \in \mathcal{T}_2$.

3. Strongly regular edges. In this section we will prove Theorem 2.4. Let $Q = [-\frac{1}{2}, \frac{1}{2}]^d$ be the basic period cell, $\tilde{Q} = [-\pi, \pi]^d$ the dual basic cell. We define the Floquet transform (e.g., [FK5])

$$(37) \quad \mathcal{F} : L^2(\mathbb{R}^d; \mathbb{C}^\nu) \rightarrow \int_{\tilde{Q}}^\oplus L^2(Q; \mathbb{C}^\nu) dk \equiv L^2(\tilde{Q}; L^2(Q; \mathbb{C}^\nu))$$

by

$$(38) \quad (\mathcal{F}\Psi)(k, x) = \widehat{\Psi}(k, x) \equiv \left(\frac{1}{2\pi}\right)^{d/2} \sum_{m \in \mathbb{Z}^d} e^{ik \cdot (x-m)} \Psi(x-m), \quad x \in Q, k \in \tilde{Q}$$

for Ψ with compact support; it extends by continuity to a unitary operator. We will write $\widehat{B} = \mathcal{F}B\mathcal{F}^*$ for an operator B on $L^2(\mathbb{R}^d; \mathbb{C}^\nu)$. The periodic operator \widetilde{W}_0 is decomposable in this direct integral representation, more precisely,

$$(39) \quad \widehat{\widetilde{W}_0} = \mathcal{F}\widetilde{W}_0\mathcal{F}^* = \int_{\tilde{Q}}^\oplus \widetilde{W}_{0,Q}(k) dk,$$

where for each $k \in \mathbb{R}^d$, we define $\widetilde{W}_{0,Q}(k)$ to be the nonnegative operator on $L^2(Q; \mathbb{C}^\nu)$, given by either $-(\nabla - ik) \cdot \frac{1}{\varepsilon_0} (\nabla - ik)$ if $W = A$ or $(\nabla - ik)^\times \frac{1}{\varepsilon_0} (\nabla - ik)^\times$ if $W = \mathbf{M}$, with periodic boundary condition; $\widetilde{W}_{0,Q}(k)$ is rigorously defined as a self-adjoint operator by the appropriate quadratic form. (As before $(\nabla - ik)^\times$ denotes the operator $(\nabla - ik)^\times \Phi = (\nabla - ik) \times \Phi$.) In addition, the map

$$(40) \quad k \in \mathbb{R}^d \longmapsto \left(\widetilde{W}_{0,Q}(k) + I\right)^{-1} \in \mathcal{L}(L^2(Q; \mathbb{C}^\nu))$$

is operator norm continuous. (See [FK5, Subsection 3.3] for details.)

If $W = \mathbf{M}$, we define $\mathbb{S}_Q(k)$ to be the closure in $L^2(Q; \mathbb{C}^3)$ of the linear space of periodic continuously differentiable functions Ψ on Q with $(\nabla - ik) \cdot \Psi = 0$, and define $\mathbf{M}_{0,Q}(k)$ as the restriction of $M_{0,Q}(k)$ to $\mathbb{S}_Q(k)$. We have

$$(41) \quad \mathcal{F}\mathbb{S} = \int_{\tilde{Q}}^\oplus \mathbb{S}_Q(k) dk, \quad \mathcal{F}\mathbf{M}_0\mathcal{F}^* = \int_{\tilde{Q}}^\oplus \mathbf{M}_{0,Q}(k) dk.$$

Thus there is a direct integral representation for W_0

$$(42) \quad \widehat{W}_0 = \mathcal{F}W_0\mathcal{F}^* = \int_{\tilde{Q}}^\oplus W_{0,Q}(k) dk \quad \text{on} \quad \int_{\tilde{Q}}^\oplus \mathcal{H}(k) dk,$$

where each $W_{0,Q}(k)$ has compact resolvent [FK3, FK5]. Here $\mathcal{H}(k)$ denotes either $L^2(Q; \mathbb{C})$ if $W = A$ or $\mathbb{S}_Q(k)$ if $W = \mathbf{M}$.

It follows [RS4, Problem 140, p. 381 and Proof of Theorem XIII.98] that $\mu_n(k)$, the n th eigenvalue of $W_{0,Q}(k)$, is a continuous function of k , and we can choose measurable functions $\psi_n : \tilde{Q} \rightarrow \mathcal{H}(k)$ such that $W_{0,Q}(k)\psi_n(k) = \mu_n(k)\psi_n(k)$ and $\{\psi_n(k)\}_{n=1,2,\dots}$ is an orthonormal basis for $\mathcal{H}(k)$ for each k . We thus have

$$(43) \quad W_{0,Q}(k) = \sum_{n=1}^{\infty} \mu_n(k)P_n(k),$$

where $P_n(k)$ denotes the orthogonal projection on the vector $\psi_n(k)$ and the series converges strongly in the domain of \widehat{W}_0 . Moreover, if $z \notin \sigma(W_0)$, say $\text{dist}(z, \sigma(W_0)) \geq \delta > 0$, we have $\text{dist}(z, \sigma(W_{0,Q}(k))) \geq \delta$ for all k and

$$(44) \quad \widehat{\check{R}_0}(z) = \int_{\tilde{Q}}^{\oplus} \check{R}_{0,Q}(k; z) dk, \quad \text{with } \check{R}_{0,Q}(k; z) = \sum_{n=1}^{\infty} \frac{1}{\mu_n(k) - z} P_n(k).$$

Thus

$$(45) \quad \left| \widehat{\check{R}_0}(z) \right| = \int_{\tilde{Q}}^{\oplus} \left| \check{R}_{0,Q}(k; z) \right| dk,$$

where $|\check{R}_{0,Q}(k; z)|$ is the operator on $L^2(Q; \mathbb{C}^\nu)$ given by

$$(46) \quad \left| \check{R}_{0,Q}(k; z) \right| = \sum_{n=1}^{\infty} \tau_n(k; z)P_n(k) \quad \text{with } \tau_n(k; z) = \frac{1}{|\mu_n(k) - z|}.$$

We also introduce

$$(47) \quad \left| \widehat{\check{R}_{0,N}}(z) \right| = \int_{\tilde{Q}}^{\oplus} \left| \check{R}_{0,Q,N}(k; z) \right| dk \quad \text{with } \left| \check{R}_{0,Q,N}(k; z) \right| = \sum_{n=1}^N \tau_n(k; z)P_n(k),$$

where $N = 1, 2, \dots$. Note that $|\check{R}_{0,N}(z)| \rightarrow |\check{R}_0(z)|$ strongly as $N \rightarrow \infty$, and for any $\Phi \in L^2(\mathbb{R}^d; \mathbb{C}^\nu)$ we have

$$(48) \quad \left\| \left| \check{R}_{0,N}(z) \right| \Phi \right\|^2 = \int_{\tilde{Q}} \left\{ \sum_{n=1}^N \tau_n(k; z)^2 \left| \langle \psi_n(k), \widehat{\Phi}(k) \rangle \right|^2 \right\} dk \nearrow \left\| \left| \check{R}_0(z) \right| \Phi \right\|^2,$$

as $N \rightarrow \infty$.

We recall that χ_0 is the characteristic function of Q . As a multiplication operator it satisfies

$$(49) \quad \begin{aligned} [\widehat{\chi_0 \widehat{\varphi}}](k, x) &= \widehat{\chi_0 \varphi}(k, x) = \left(\frac{1}{2\pi} \right)^{d/2} e^{ik \cdot x} \varphi(x) \\ &= \left(\frac{1}{2\pi} \right)^d \int_{\tilde{Q}} e^{i(k-k') \cdot x} \widehat{\varphi}(k', x) dk', \end{aligned}$$

for any $\varphi \in L^2(\mathbb{R}^d; \mathbb{C}^\nu)$, with $x \in Q$, $k \in \tilde{Q}$. We set $K(z) = \chi_0 |\check{R}_0(z)| \chi_0$, $K_N(z) = \chi_0 |\check{R}_{0,N}(z)| \chi_0$. Putting together (47) and (49), we can see that $K_N(z)$ is a bounded integral operator on $L^2(\tilde{Q} \times Q; \mathbb{C}^\nu) \cong L^2(\tilde{Q}; L^2(Q; \mathbb{C}^\nu))$ with kernel

$$(50) \quad K_N(z)(k, x; p, y) = \left(\frac{1}{2\pi} \right)^{2d} e^{i(k \cdot x - p \cdot y)} \int_{\tilde{Q}} \left\{ \sum_{n=1}^N \tau_n(q; z) \psi_n(q, x) \overline{\psi_n(q, y)} \right\} dq.$$

The following lemma will help us separate the contributions of different bands. We use $\|T\|_2 = (\text{Tr } T^*T)^{1/2}$ to denote the Hilbert–Schmidt norm of an operator T .

LEMMA 3.1.

(i) For each $N = 1, 2, \dots$ we have

$$(51) \quad \|K_N(z)\|_2^2 = \left(\frac{1}{2\pi}\right)^{2d} \sum_{n,m=1}^N \int_{\tilde{Q}} \int_{\tilde{Q}} \tau_n(k; z) \tau_m(p; z) |\langle \psi_n(k), \psi_m(p) \rangle|^2 dk dp.$$

(ii) We have

$$(52) \quad \|K(z)\|_2 \leq \liminf_{N \rightarrow \infty} \|K_N(z)\|_2.$$

(iii) If $d = 3$ and $z = -1$, we have

$$(53) \quad \|K(-1)\|_2^2 = \left(\frac{1}{2\pi}\right)^6 \sum_{n,m=1}^\infty \int_{\tilde{Q}} \int_{\tilde{Q}} \tau_n(k; -1) \tau_m(p; -1) |\langle \psi_n(k), \psi_m(p) \rangle|^2 dk dp.$$

Proof. It follows from (50) that

$$(54) \quad \|K_N(z)\|_2^2 = \int_{\tilde{Q} \times Q} \int_{\tilde{Q} \times Q} |K_N(z)(k, x; p, y)|^2 dp dy dk dx,$$

from which (51) follows by an explicit computation.

Since $K_N(z) \rightarrow K(z)$ strongly as $N \rightarrow \infty$, (52) follows from Fatou’s lemma.

To prove (53), first note it follows from (48) that

$$(55) \quad \left\| \chi_0 \left| \check{R}_{0,N}(z) \right| \chi_0 \Phi \right\| \leq \left\| \check{R}_{0,N}(z) \right| \chi_0 \Phi \right\| \leq \left\| \check{R}_0(z) \chi_0 \Phi \right\|$$

for any $\Phi \in L^2(\mathbb{R}^d; \mathbb{C}^\nu)$, so we can conclude that

$$(56) \quad \sup_N \|K_N(z)\|_2 \leq \left\| \check{R}_0(z) \right| \chi_0 \right\|_2.$$

We now restrict ourselves to $d = 3$ and $z = -1$. In this case $|\check{R}_0(-1)| = \check{R}_0(-1)$ and the operator $\check{R}_0(-1)\chi_0$ is Hilbert–Schmidt [FK3, Proposition 42], [FK5, Theorem 18]. We have $\tau_n(k; -1) \geq 1 > 0$, so it follows from (56) that the series in the right-hand side of (53) is absolutely convergent. As $\|K_N(-1) - K_M(-1)\|_2^2$ is given by the obvious analogue of (51), we can conclude that the $K_N(-1)$ form a Cauchy sequence in the Hilbert–Schmidt norm; since $K_N(-1) \rightarrow K(-1)$ strongly, it follows that $\|K_N(-1) - K(-1)\|_2 \rightarrow 0$, so (53) follows from (51). \square

We are now ready to prove Theorem 2.4; we will do so for the left edge a , the proof for the right edge b being similar. So let $d = 3$ and let $n_1 \leq n_0$ be as in the discussion below Definition 2.2 and let $\eta \in (0, b - a)$. We have

$$(57) \quad K(a + \eta) = K_{n_1-1}(a + \eta) + \{K_{n_0}(a + \eta) - K_{n_1-1}(a + \eta)\} + \{K(a + \eta) - K_{n_0}(a + \eta)\}.$$

Using (51) we get

$$(58) \quad \|K_{n_1-1}(a + \eta)\|_2 \leq \left(\frac{n_1 - 1}{c_{n_1-1}}\right),$$

where

$$(59) \quad c_{n_1-1} = \min_{n=1, \dots, n_1-1} \left(a - \max_{k \in \tilde{Q}} \mu_n(k) \right) > 0$$

by the definition of n_1 . If $n > n_0$ we have

$$(60) \quad \begin{aligned} \tau_n(k; a + \eta) &= \frac{\mu_n(k) + 1}{\mu_n(k) - (a + \eta)} \tau_n(k; -1) \leq \left(1 + \frac{1 + a}{\mu_n(k) - (a + \eta)} \right) \tau_n(k; -1) \\ &\leq \left(1 + \frac{1 + a}{b - (a + \eta)} \right) \tau_n(k; -1), \end{aligned}$$

so it follows from (52), (51), (53), and (56) that

$$(61) \quad \limsup_{\eta \rightarrow 0} \|K(a + \eta) - K_{n_0}(a + \eta)\|_2 \leq \left(1 + \frac{1 + a}{b - a} \right) \|\check{R}_0(-1)\chi_0\|_2 < \infty.$$

Finally, it follows from (51) and Assumption (25) that

$$(62) \quad \limsup_{\eta \rightarrow 0} \|K_{n_0}(a + \eta) - K_{n_1-1}(a + \eta)\|_2 \leq \left(\frac{1}{2\pi} \right)^3 \sum_{n=n_1-1}^{n_0} \int_{\tilde{Q}} \frac{1}{a - \mu_n(k)} dk < \infty.$$

Combining (57), (58), (59), (61), and (62) we get $\limsup_{\eta \rightarrow 0} \|K(a + \eta)\|_2 < \infty$, which is the same as (26), so Theorem 2.4 is proven.

4. Bounded, relatively compact perturbations. Let $H_g = H_0 + gV$, where H_0 and V are self-adjoint operators, H_0 has a gap (a, b) in its spectrum, $V \geq 0$ is bounded and relatively compact with respect to H_0 , and g is a real number. By [RS4, Section XIII.4, Corollary 2], we have $\sigma_{\text{ess}}(H_g) = \sigma_{\text{ess}}(H_0)$, so the spectrum of the operator H_g in the gap (a, b) consists of isolated eigenvalues of finite multiplicity, which can only accumulate at the edges a and b .

We now apply the Birman–Schwinger method. The eigenvalue problem

$$(63) \quad H_0\psi + gV\psi = \lambda\psi, \quad \lambda \in (a, b)$$

can be rewritten as

$$(64) \quad \psi = -gR_0(\lambda)V\psi, \quad \text{where } R_0(\lambda) = (H_0 - \lambda I)^{-1}.$$

If we set

$$(65) \quad \mathcal{R}(\lambda) = \mathcal{R}_{H_0, V}(\lambda) = -\sqrt{V}R_0(\lambda)\sqrt{V},$$

we obtain

$$(66) \quad \mathcal{R}(\lambda)\varphi = \frac{1}{g}\varphi \quad \text{for } \varphi = \sqrt{V}\psi.$$

The Birman–Schwinger operator $\mathcal{R}(\lambda)$ is a compact self-adjoint operator. We have the following lemma [Kl].

LEMMA 4.1. *Let $g \neq 0$. Then $\lambda \in (a, b)$ is an eigenvalue of H_g with multiplicity m if and only if $1/g$ is an eigenvalue of $\mathcal{R}(\lambda)$ with multiplicity m .*

Proof. We give the proof for completeness. Let $\lambda \in (a, b)$ be an eigenvalue for H_g with eigenfunction ψ , i.e., (63) holds with $\Psi \neq 0$. It follows from (64)–(66) that $1/g$ is an eigenvalue of $\mathcal{R}(\lambda)$ with eigenfunction $\varphi = \sqrt{V}\psi$. Since $\psi = -gR_0(\lambda)\sqrt{V}\varphi$, we clearly have $m_\lambda \leq m_{1/g}$, where m_λ and $m_{1/g}$ denote the multiplicity of λ and $1/g$ as eigenvalues of H_g and $\mathcal{R}(\lambda)$, respectively.

Conversely, if $1/g$ is an eigenvalue of $\mathcal{R}(\lambda)$ with eigenfunction φ , then if we set $\psi = -gR_0(\lambda)\sqrt{V}\varphi$, we have $\sqrt{V}\psi = g\mathcal{R}(\lambda)\varphi = \varphi$, so we get $(H_0 - \lambda I)\psi = -g\sqrt{V}\varphi = gV\psi$, which is the same as (63). It also follows that $m_{1/g} \leq m_\lambda$. \square

Given λ in the gap (a, b) , let $r_1^+(\lambda) \geq r_2^+(\lambda) \geq \dots \geq 0$ and $r_1^-(\lambda) \leq r_2^-(\lambda) \leq \dots \leq 0$ be infinite sequences of, respectively, the positive and negative eigenvalues of the operator $\mathcal{R}(\lambda)$. If we have a finite number of either positive or negative eigenvalues, we complete the sequence by assigning the value 0. The sequence $r_n^-(\lambda)$, $n = 1, 2, \dots$, can be obtained by applying the min-max principle to the operator $\chi_{(-\infty, 0]}(\mathcal{R}(\lambda))\mathcal{R}(\lambda)$; similarly, we obtain $-r_n^+(\lambda)$, $n = 1, 2, \dots$, by applying the min-max principle to the operator $-\chi_{[0, \infty)}(\mathcal{R}(\lambda))\mathcal{R}(\lambda)$.

It turns out that it is more convenient to first study the dependence of the eigenvalues $r_n^\pm(\lambda)$ of the operator $\mathcal{R}(\lambda)$ on the parameter λ , and then use Lemma 4.1 to obtain information about the eigenvalues of H_g in the gap (a, b) (see [Kl, ADH]).

LEMMA 4.2. *The functions $r_n^\pm(\lambda)$ are monotonically decreasing, continuous functions of $\lambda \in (a, b)$ for each $n = 1, 2, \dots$*

Proof. The lemma follows from the fact that the the map $\lambda \in (a, b) \rightarrow \mathcal{R}(\lambda)$ is norm continuous and operator monotone decreasing. \square

The following proposition is an immediate consequence of Lemmas 4.1 and 4.2; it gives a criterion for the absence of eigenvalues of H_g in the gap (a, b) for small g .

PROPOSITION 4.3. *The following statements are equivalent:*

- (i) *The operator H_g has no eigenvalues in the gap (a, b) for small g .*
- (ii) *We have*

$$(67) \quad \max_{\lambda \in (a, b)} \|\mathcal{R}(\lambda)\| = \max \{r_1^+(a + 0), -r_1^-(b - 0)\} < \infty.$$

We can summarize some important conclusions of the Birman–Schwinger method in the following theorem, which is an immediate consequence of Lemma 4.1 (including the considerations right before it) and Lemma 4.2.

THEOREM 4.4. *Let H_0 and V be self-adjoint operators. Suppose that H_0 has a gap (a, b) in its spectrum and V is bounded, relatively compact with respect to H_0 ; set $H = H_0 + V$. Then:*

(i) *If $V \geq 0$, the only possible point of accumulation of $\sigma(H) \cap (a, b)$ is a . In this case the eigenvalues $\lambda_1 \geq \lambda_2 \geq \dots$ of the operator H in the gap (a, b) coincide with the set of the solutions of the equations*

$$(68) \quad r_n^+(\lambda) = 1, \quad n = 1, 2, \dots,$$

where $r_n^+(\lambda)$ are the positive eigenvalues of the operator $\mathcal{R}(\lambda)$ defined by (65). Moreover, if $\varphi(\lambda)$ is an eigenmode of the operator $\mathcal{R}(\lambda)$ with eigenvalue $r_n^+(\lambda) = 1$, then

$$(69) \quad \psi = (H_0 - \lambda I)^{-1} \sqrt{V}\varphi(\lambda)$$

is an exponentially localized eigenmode of the operator H with eigenvalue λ .

(ii) *If $V \leq 0$, the only possible point of accumulation of $\sigma(H) \cap (a, b)$ is b . In this case the eigenvalues $\lambda_1 \leq \lambda_2 \leq \dots$ of the operator H in the gap (a, b) coincide*

with the set of the solutions of the equations

$$(70) \quad r_n^-(\lambda) = -1, \quad n = 1, 2, \dots,$$

where $r_n^-(\lambda)$ are the negative eigenvalues of the operator $\mathcal{R}(\lambda)$ defined by (65). Moreover, if $\varphi(\lambda)$ is an eigenmode of the operator $\mathcal{R}(\lambda)$ with eigenvalue $r_n^-(\lambda) = -1$, then

$$(71) \quad \psi = -(H_0 - \lambda I)^{-1} \sqrt{-V} \varphi(\lambda)$$

is an exponentially localized eigenmode of the operator H with eigenvalue λ .

In order to estimate the number of eigenvalues of the operator $H = H_0 + V$ in the gap (a, b) , we introduce a counting function $\mathcal{N}_{H_0, V}^+$, which will count the eigenvalues generated in the gap. We start with a descriptive definition which will be followed by a rigorous one. We pick a number $0 < \eta < (b - a)$ and put an observer at the point $a + \eta$. As g changes gradually from 0 to 1, the operator H_g develops eigenvalues in the gap which split off the endpoint a and move toward the point b . The observer counts how many times an eigenvalue of H_g passes through the point $a + \eta$ as g changes from 0 to 1; the number of such events as a function of $a + \eta$ will be called the (left-edge) counting function and denoted by $\mathcal{N}_{H_0, V}^+(a + \eta)$.

DEFINITION 4.5. For $0 < \eta < (b - a)$ we define the (left-edge) counting function $\mathcal{N}_{H_0, V}^+(a + \eta)$ as the number of $g' \in (0, 1]$, such that $a + \eta$ is an eigenvalue of $H_{g'}$. (If $a + \eta$ is an eigenvalue of $H_{g'}$ of multiplicity m , g' must be counted m times.)

Similarly, we define the (right-edge) counting function $\mathcal{N}_{H_0, V}^-(b - \eta)$ as the number of $g' \in [-1, 0)$, such that $b - \eta$ is an eigenvalue of $H_{g'}$.

The counting function can be estimated as follows.

LEMMA 4.6. Letting $0 < \eta < (b - a)$, we have

$$(72) \quad \mathcal{N}_{H_0, V}^+(a + \eta) \leq \text{Tr} \left(\{ \mathcal{R}_{H_0, V}(a + \eta) \}^2 \right)$$

and

$$(73) \quad \mathcal{N}_{H_0, V}^-(b - \eta) \leq \text{Tr} \left(\{ \mathcal{R}_{H_0, V}(b - \eta) \}^2 \right).$$

Proof. It follows from Lemma 4.1 that

$$(74) \quad \mathcal{N}_{H_0, V}^+(a + \eta) = \# \{ \mu \geq 1; \mu \text{ eigenvalue of } \mathcal{R}_{H_0, V}(a + \eta) \}$$

$$(75) \quad \leq \text{Tr} \left(\{ \mathcal{R}_{H_0, V}(a + \eta) \}^2 \right). \quad \square$$

The counting function can be used to estimate the number of eigenvalues of H in the gap.

LEMMA 4.7. Letting $0 < \eta < (b - a)$, we have

$$(76) \quad N_{H_0 + V}(a + \eta, b) \leq \mathcal{N}_{H_0, V}^+(a + \eta)$$

and

$$(77) \quad N_{H_0 - V}(a, b - \eta) \leq \mathcal{N}_{H_0, V}^-(b - \eta).$$

Proof. We have

$$\begin{aligned}
 N_{H_0+V}(a+\eta, b) &= \#\{\lambda \in (a+\eta, b); \lambda \text{ eigenvalue of } H_0 + V\} \\
 (78) \qquad &= \#\{\lambda \in (a+\eta, b); 1 \text{ eigenvalue of } \mathcal{R}_{H_0, V}(\lambda)\} \\
 (79) \qquad &\leq \#\{\mu \geq 1; \mu \text{ eigenvalue of } \mathcal{R}_{H_0, V}(a+\eta)\} = \mathcal{N}_{H_0, V}^+(a+\eta),
 \end{aligned}$$

where (78) follows from Lemma 4.1 and the inequality in (79) is a consequence of Lemma 4.2. \square

The counting functions have the important property of being monotone in the operator V [ADH, Corollary 1.7].

LEMMA 4.8. *Let $V_2 \geq V_1 \geq 0$ be bounded and relatively compact with respect to H_0 . Then*

$$(80) \qquad \mathcal{N}_{H_0, V_1}^+(a+\eta) \leq \mathcal{N}_{H_0, V_2}^+(a+\eta)$$

and

$$(81) \qquad \mathcal{N}_{H_0, V_1}^-(b-\eta) \leq \mathcal{N}_{H_0, V_2}^-(b-\eta).$$

Proof. The statement follows from (74) and Theorem A.2. \square

5. Reduction to compact perturbations. If the medium described by $\varepsilon(x)$ (as in (4)) was obtained from the background medium, described by a function $\varepsilon_0(x)$ as in (4)—not necessarily periodic—by the insertion of a defect, we can write $W = W_0 + Q$, but the perturbation Q is unbounded. This can be remedied by working with the resolvents.

PROPOSITION 5.1. *Suppose $d \leq 3$. Let $\varepsilon(x)$ and $\varepsilon_0(x)$, as in (4), differ by a defect. If we set $H = (W + I)^{-1}$ and $H_0 = (W_0 + I)^{-1}$, then $V = H - H_0$ is a Hilbert–Schmidt operator.*

Proof. Let $\Theta(x) = 1/\varepsilon(x) - 1/\varepsilon_0(x)$; by our hypotheses it is a bounded measurable function with compact support. We clearly have $Y \equiv W - W_0 = (\nabla^\sharp)^* \Theta \nabla^\sharp$ as quadratic forms on the common quadratic form domain of W and W_0 , where $\nabla^\sharp = \nabla$ if $W = A$ and $\nabla^\sharp = \nabla^\times$ if $W = M$. Thus, $V = -HVH_0 = -T^* \Theta T_0$, with $T = \chi \nabla^\sharp H$ and $T_0 = \chi \nabla^\sharp H_0$, where χ is the characteristic function of an open, bounded set containing the support of Θ .

Since T and T_0 are Hilbert–Schmidt operators by [FK4, Lemma 6], we can conclude that V is Hilbert–Schmidt. \square

Proposition 5.1 allows us to define counting functions for the operator W . Note that $((b+1)^{-1}, (a+1)^{-1})$ is a gap in the spectrum of H_0 if (a, b) is a gap in the spectrum of W_0 .

DEFINITION 5.2. *Let W, W_0, H, H_0, V be as in Proposition 5.1. Suppose (a, b) is a gap in the spectrum of W_0 , and let $0 < \eta \leq b - a$. If the defect is positive, we define the left-edge counting function for W by*

$$(82) \qquad \mathcal{N}_W^+(a+\eta) = \mathcal{N}_{H_0, V}^-((a+1+\eta)^{-1}).$$

Similarly, if the defect is negative, we define the right-edge counting function for W by

$$(83) \qquad \mathcal{N}_W^-(b-\eta) = \mathcal{N}_{H_0, V}^+((b+1-\eta)^{-1}).$$

Lemmas 4.7 and 4.8 have the following immediate counterparts for acoustic and Maxwell operators.

LEMMA 5.3. *Suppose $d \leq 3$. Let $\varepsilon(x)$ and $\varepsilon_0(x)$, as in (4) and (30), differ by a defect. Assume (a, b) is a gap in the spectrum of W_0 , and let $0 < \eta \leq b - a$. If the defect is positive we have*

$$(84) \quad N_W(a + \eta, b) \leq \mathcal{N}_W^+(a + \eta).$$

Similarly, if the defect is negative we have

$$(85) \quad N_W(a, b - \eta) \leq \mathcal{N}_W^-(b - \eta).$$

LEMMA 5.4. *Suppose $d \leq 3$. Let $\varepsilon_i(x)$, $i = 0, 1, 2$, be as in (4), differing from each other by a defect, and let W_i , $i = 0, 1, 2$, be the corresponding operators. Assume (a, b) is a gap in the spectrum of W_0 , and let $0 < \eta \leq b - a$. Then, if $\varepsilon_2(x) \leq \varepsilon_1(x) \leq \varepsilon_0(x)$ we have*

$$(86) \quad \mathcal{N}_{W_1}^+(a + \eta) \leq \mathcal{N}_{W_2}^+(a + \eta).$$

Similarly, if $\varepsilon_2(x) \geq \varepsilon_1(x) \geq \varepsilon_0(x)$ we have

$$(87) \quad \mathcal{N}_{W_1}^-(b - \eta) \leq \mathcal{N}_{W_2}^-(b - \eta).$$

6. Smooth defects. We call a defect *smooth* if the function $\theta(x)$ in (30) is continuously differentiable with compact support. In this section we will prove some lemmas concerning smooth defects. Theorem 2.5 is proved in the next section by a reduction to the case of smooth defects.

LEMMA 6.1. *Suppose $d \leq 3$. Let $\varepsilon(x)$ and $\varepsilon_0(x)$, as in (4) and (30), differ by either a positive or negative smooth defect, and set χ to be the characteristic function of an open, bounded set containing the support of θ . Suppose (a, b) is a gap in the spectrum of W_0 , and let $0 < \eta \leq b - a$. Then:*

(i) *For a negative defect we have*

$$(88) \quad \mathcal{N}_W^-(b - \eta) \leq (b + 1 - \eta)^2 \text{Tr} \left(\chi \check{R}_0(b - \eta) \check{R}(-1) \tilde{Y}^2 \check{R}(-1) \check{R}_0(b - \eta) \chi \right).$$

(ii) *For a positive defect we have*

$$(89) \quad \mathcal{N}_W^+(a + \eta) \leq (a + 1 + \eta)^2 \text{Tr} \left(\chi \check{R}_0(a + \eta) \check{R}(-1) \tilde{Y}^2 \check{R}(-1) \check{R}_0(a + \eta) \chi \right).$$

Proof. Let us suppose the smooth defect is negative, the other case being similar. We take H , H_0 , V as in Proposition 5.1, so $V \geq 0$ is a Hilbert–Schmidt operator. Thus, given $0 < \eta \leq b - a$, we can apply Lemma 4.6 and (83) to conclude

$$(90) \quad \mathcal{N}_W^-(b - \eta) \leq \text{Tr} \left(\left\{ \sqrt{V} (H_0 - (b + 1 - \eta)^{-1} I)^{-1} \sqrt{V} \right\}^2 \right)$$

$$(91) \quad = \text{Tr} \left(\left\{ V (H_0 - (b + 1 - \eta)^{-1} I)^{-1} \right\}^2 \right).$$

But

$$(92) \quad \begin{aligned} (H_0 - (b + 1 - \eta)^{-1}I)^{-1} &= -(b + 1 - \eta) (W_0 + I) (W_0 - (b - \eta)I)^{-1} \\ &= -(b + 1 - \eta) (W_0 + I) R_0(b - \eta), \end{aligned}$$

so

$$(93) \quad V (H_0 - (b + 1 - \eta)^{-1}I)^{-1} = -(b + 1 - \eta) (W + I)^{-1} Y R_0(b - \eta)$$

$$(94) \quad = -(b + 1 - \eta) R(-1) Y R_0(b - \eta).$$

Note that $\chi \check{R}_0(b - \eta)$ is Hilbert–Schmidt (see [FK3, Proposition 42] and [FK5, Theorem 18]), and since the defect is smooth, $R(-1)Y$ is a bounded operator (see [FK4, Proof of Lemma 6]). Thus

$$(95) \quad \mathcal{N}_W^-(b - \eta) \leq (b + 1 - \eta)^2 \text{Tr} \left(\{R(-1)Y \chi R_0(b - \eta)\}^2 \right)$$

$$(96) \quad = (b + 1 - \eta)^2 \text{Tr} \left(\{ \check{R}(-1) \tilde{Y} \chi \check{R}_0(b - \eta) \}^2 \right)$$

$$(97) \quad = (b + 1 - \eta)^2 \text{Tr} \left(\{ \chi \check{R}_0(b - \eta) \check{R}(-1) \tilde{Y} \}^2 \right)$$

$$(98) \quad \leq (b + 1 - \eta)^2 \text{Tr} \left(\chi \check{R}_0(b - \eta) \check{R}(-1) \tilde{Y}^2 \check{R}(-1) \check{R}_0(b - \eta) \chi \right),$$

where we used the inequality $|\text{Tr} B^2| \leq \text{Tr} B^* B$ to get (98).

The lemma is proven. \square

We now need to estimate from above the positive operator $\check{R}(-1) \tilde{Y}^2 \check{R}(-1)$. To do so we pick $\delta > 0$ and introduce the positive self-adjoint operator $\Gamma = \Gamma_\delta$ given by multiplication by the function

$$(99) \quad \gamma(x) = \gamma_\delta(x) = \sum_{m \in \mathbb{Z}^d} \gamma_m \chi_m(x), \quad \text{with } \gamma_m = (1 + |m|)^{d+\delta/2}.$$

Note that

$$(100) \quad \gamma_{m+n} \leq \gamma_m \gamma_n \quad \text{for all } m, n \in \mathbb{Z}^d.$$

LEMMA 6.2. *Let $\varepsilon(x)$ and $\varepsilon_0(x)$, as in (4), (30), and (32), differ by a smooth defect, with $\theta(x)$ vanishing outside a cube Λ_ℓ of side $\ell > 0$ centered at 0. Suppose $d \leq 3$ and let $0 < \delta \leq 1$. Then there exists a finite constant K , such that*

$$(101) \quad \check{R}(-1) \tilde{Y}^2 \check{R}(-1) \leq C \|\theta\|_\infty^2 (\ell + 2)^{2d+\delta} \Gamma_\delta^{-2},$$

with

$$(102) \quad C = \left\{ 1 + K \left[1 + \varepsilon_-^{-(2d+\delta)} \right]^{1/2} \left[1 + \frac{\sqrt{\varepsilon_+}}{\varepsilon_{0,-}} \left(\sqrt{\varepsilon_-} + \frac{1}{\sqrt{\varepsilon_-}} \right) \frac{\|\nabla\theta\|_\infty}{\|\theta\|_\infty} \right] \right\}^2.$$

Proof. In view of Corollary C.2 it suffices to estimate $\|\tilde{Y} \check{R}(-1) \Gamma\|_{\mathcal{F}}$. (See C for the notation.) Let us consider the case $W = A$, the case $W = \mathbf{M}$ being similar. In this case

$$(103) \quad Y = -\nabla \cdot \frac{\theta(x)}{\varepsilon_0(x)} \nabla = \theta W - \frac{1}{\varepsilon_0} (\nabla\theta) \cdot \nabla$$

hence,

$$(104) \quad \check{Y}\check{R}(-1) = \theta - \theta\check{R}(-1) - \frac{1}{\varepsilon_0} (\nabla\theta) \cdot \nabla\check{R}(-1).$$

Clearly,

$$(105) \quad \|\theta\Gamma\|_{\mathcal{F}} \leq \|\theta\|_{\infty} (\ell + 2)^{d/2} \left(1 + \frac{\sqrt{d}}{2}(\ell + 1)\right)^{d+\delta/2} \leq \|\theta\|_{\infty} (\ell + 2)^{d+\delta/2},$$

where we used $d \leq 3$. A straightforward calculation using Proposition B.1 and (100) gives

$$(106) \quad \left\| \theta\check{R}(-1)\Gamma \right\|_{\mathcal{F}} \leq \|\theta\|_{\infty} \left[\sum_{\substack{n \in \mathbb{Z}^d \cap \Lambda_{\ell+1} \\ m \in \mathbb{Z}^d}} \left\| \chi_n \check{R}(-1) \chi_m \right\|^2 \gamma_m^2 \right]^{1/2}$$

$$(107) \quad \leq \alpha_d \|\theta\|_{\infty} \left[\sum_{\substack{n \in \mathbb{Z}^d \cap \Lambda_{\ell+1} \\ m \in \mathbb{Z}^d}} e^{-2\beta|m-n|} (1 + |m|)^{d+\delta} \right]^{1/2}$$

$$(108) \quad \leq \alpha_d \|\theta\|_{\infty} (\ell + 2)^{d+\delta/2} \left[\sum_{m \in \mathbb{Z}^d} e^{-2\beta|m|} (1 + |m|)^{d+\delta} \right]^{1/2}$$

$$(109) \quad \leq K_1 \|\theta\|_{\infty} (\ell + 2)^{d+\delta/2} \left[1 + \beta^{-(2d+\delta)} \right]^{1/2} \\ \leq K \|\theta\|_{\infty} (\ell + 2)^{d+\delta/2} \left[1 + \varepsilon_-^{-(2d+\delta)} \right]^{1/2},$$

where α_d and β are as in Proposition B.1, and K_1, K are finite constants, independent of all parameters for $d \leq 3$ and $0 < \delta \leq 1$. Similarly,

$$(110) \quad \left\| \frac{1}{\varepsilon_0} (\nabla\theta) \cdot \nabla\check{R}(-1)\Gamma \right\|_{\mathcal{F}} \\ \leq K \left[1 + \varepsilon_-^{-(2d+\delta)} \right]^{1/2} \frac{\sqrt{\varepsilon_+}}{\varepsilon_{0,-}} \left(\sqrt{\varepsilon_-} + \frac{1}{\sqrt{\varepsilon_-}} \right) \|\nabla\theta\|_{\infty} (\ell + 2)^{d+\delta/2}.$$

The estimate (101) follows from (105), (109), (110), and Corollary C.2. □

7. Regular edges. We are now ready to prove Theorem 2.5. We will consider the case when the right edge b is regular and the defect is negative, the other case being analogous. Thus $\theta(x) \leq 0$, vanishing outside a cube Λ_{ℓ} of side $\ell > 0$, which we take to be centered at 0 without loss of generality. Note $\theta_+ = 0$ and $\varepsilon_- = \varepsilon_{0,-}$.

We start by reducing to the case of a smooth defect. We pick a continuously differentiable function $f(t)$ of one real variable, with $0 \leq f(t) \leq 1$ for all t , $f(t) = 1$ for $|t| \leq \frac{\ell}{2}$, $f(t) = 0$ for $|t| \geq \frac{\ell+1}{2}$, and $|f'(t)| \leq 3$ for all t . (Such a function always exists.) We now set $\theta_s(x) = \theta_- \prod_{i=1}^d f(x_i)$; it is a continuously differentiable function vanishing outside the cube $\Lambda_{\ell+1}$ centered at 0, with $\|\theta_s\|_{\infty} = |\theta_-|$ and

$\|\nabla\theta_s\|_\infty \leq 3\sqrt{d}|\theta_-|$. Moreover, $\theta(x) \geq \theta_s(x)$ for all x . We set $\varepsilon_s(x) = \frac{\varepsilon_0(x)}{1+\theta_s(x)}$ and let W_s denote the corresponding acoustic or Maxwell operator. Note $\varepsilon_{s,\pm} = \varepsilon_\pm$ by (32). If $d \leq 3$ and $0 < \delta \leq 1$ for any given $0 < \eta \leq b - a$ and we get from Lemmas 5.3, 5.4, 6.1, and 6.2 that

$$(111) \quad N_W(a, b - \eta) \leq \mathcal{N}_{W_s}^-(b - \eta) \leq (b + 1 - \eta)^2 C_{d,\varepsilon_0,\pm,\theta_-,\delta} \theta_-^2 (\ell + 3)^{2d+\delta} \text{Tr} \left(\chi \check{R}_0(b - \eta) \Gamma_\delta^{-2} \check{R}_0(b - \eta) \chi \right),$$

where

$$(112) \quad C_{d,\varepsilon_0,\pm,\theta_-,\delta} = \left\{ 1 + K \left[1 + \varepsilon_{0,-}^{-(2d+\delta)} \right]^{1/2} \left[1 + 3\sqrt{d} \frac{\sqrt{\varepsilon_+}}{\varepsilon_{0,-}} \left(\sqrt{\varepsilon_{0,-}} + \frac{1}{\sqrt{\varepsilon_{0,-}}} \right) \right] \right\}^2,$$

and χ is the characteristic function of the cube $\Lambda_{\ell+1}$.

Recalling (99), we see that

$$(113) \quad \begin{aligned} &\text{Tr} \left(\chi \check{R}_0(b - \eta) \Gamma_\delta^{-2} \check{R}_0(b - \eta) \chi \right) \\ &= \sum_{m \in \mathbb{Z}^d} (1 + |m|)^{-(d+\delta)} \text{Tr} \left(\chi \check{R}_0(b - \eta) \chi_m \check{R}_0(b - \eta) \chi \right). \end{aligned}$$

We have

$$(114) \quad \text{Tr} \left(\chi \check{R}_0(b - \eta) \chi_m \check{R}_0(b - \eta) \chi \right) = \text{Tr} \left(\chi_m \check{R}_0(b - \eta) \chi \check{R}_0(b - \eta) \chi_m \right)$$

$$(115) \quad \leq \sum_{n \in \mathbb{Z}^d \cap \Lambda_{\ell+2}} \text{Tr} \left(\chi_m \check{R}_0(b - \eta) \chi_n \check{R}_0(b - \eta) \chi_m \right)$$

$$(116) \quad \leq 4 \sum_{n \in \mathbb{Z}^d \cap \Lambda_{\ell+2}} \left\{ \text{Tr} \left[\left(\chi_m \left| \check{R}_0(b - \eta) \right| \chi_m \right)^2 \right] \right\}^{1/2} \left\{ \text{Tr} \left[\left(\chi_n \left| \check{R}_0(b - \eta) \right| \chi_n \right)^2 \right] \right\}^{1/2}$$

$$(117) \quad \leq 4(\ell + 3)^d \text{Tr} \left[\left(\chi_0 \left| \check{R}_0(b - \eta) \right| \chi_0 \right)^2 \right],$$

where (117) follows from Lemma D.1, and (118) is a consequence of the periodicity of the operator $\check{R}_0(b - \eta)$.

Combining (111), (113), and (118) and using

$$(118) \quad \sum_{m \in \mathbb{Z}^d} (1 + |m|)^{-(d+\delta)} \leq \frac{K_2}{\delta}$$

with a fixed constant K_2 for $d \leq 3$ and $0 < \delta \leq 1$, we get

$$(119) \quad \begin{aligned} N_W(a, b - \eta) &\leq \frac{4K_2}{\delta} (b + 1 - \eta)^2 C_{d,\varepsilon_0,\pm,\theta_-,\delta} \theta_-^2 (\ell + 3)^{3d+\delta} \text{Tr} \left[\left(\chi_0 \left| \check{R}_0(b - \eta) \right| \chi_0 \right)^2 \right], \end{aligned}$$

so (35) follows.

Theorem 2.5 is proven.

Appendix A. Minimax principle in a spectral gap. We use the following version of the minimax principle.

THEOREM A.1. *Let A be a bounded from below self-adjoint operator, and let $\lambda_1 \leq \lambda_2 \leq \dots$ be the set of the eigenvalues of A (taking into account their multiplicity) in the half-interval $(-\infty, \inf \{\sigma_{\text{ess}}(A)\})$. If the set of those eigenvalues is finite, i.e., for some finite positive integer n the numbers $\lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_n$ are the only eigenvalues (taking in account the multiplicity) of the operator A below $\inf \{\sigma_{\text{ess}}(A)\}$, we set $\lambda_{n+1} = \lambda_{n+2} = \dots = \inf \{\sigma_{\text{ess}}(A)\}$. For each $n = 1, 2, \dots$, we have*

$$(A.120) \quad \lambda_n = \inf_{L \subset \mathcal{D}(A): \dim L = n} \left[\sup_{\psi \in L: \|\psi\|=1} \langle \psi, A\psi \rangle \right].$$

Proof. Let us denote by μ_n the right-hand side of (A.120) we must show $\mu_n = \lambda_n$ for all $n = 1, 2, \dots$. It follows immediately from [RS4, Theorem XIII.3] that for $L \subset \mathcal{D}(A)$ with $\dim L = n$, we have

$$(A.121) \quad \lambda_n \leq \sup_{\psi \in L: \|\psi\|=1} \langle \psi, A\psi \rangle, \text{ so } \lambda_n \leq \mu_n.$$

To prove the opposite inequality we must consider two separate cases. Let $\alpha_0 = \inf \{\sigma_{\text{ess}}(A)\}$. If $\lambda_n < \alpha_0$, we introduce the space L_n which is the span of the eigenvectors corresponding to the eigenvalues $\lambda_1 \leq \dots \leq \lambda_n$, note $\dim L = n$. It then follows from the definition of μ_n that

$$(A.122) \quad \mu_n \leq \sup_{\psi \in L_n: \|\psi\|=1} \langle \psi, A\psi \rangle = \lambda_n.$$

If $\lambda_n = \alpha_0$, we have $\text{Tr } \chi_{[\alpha_0, \alpha_0 + \delta)}(A) = \infty$ for any $\delta > 0$. This means that given any $\delta > 0$, we can pick $L \subset \mathcal{D}(A)$ with $\dim L = n$, such that $\sup_{\psi \in L: \|\psi\|=1} \langle \psi, A\psi \rangle \leq \alpha_0 + \delta$, so $\mu_n \leq \alpha_0 + \delta$. Thus $\mu_n \leq \alpha_0 = \lambda_n$. \square

Now for a compact self-adjoint operator A let $\lambda_1^+(A) \geq \lambda_2^+(A) \geq \dots \geq 0$ and $\lambda_1^-(A) \leq \lambda_2^-(A) \leq \dots \leq 0$ be infinite sequences of, respectively, the positive and negative eigenvalues of the operator A . If we have a finite number of either positive or negative eigenvalues, we complete the sequence by assigning the value 0. The sequence $\lambda_n^-(A)$, $n = 1, 2, \dots$, can be obtained by applying the min-max principle to the operator $\chi_{(-\infty, 0]}(A)A$; similarly, we obtain $-\lambda_n^+(A)$, $n = 1, 2, \dots$, by applying the min-max principle to the operator $-\chi_{[0, \infty)}(A)A$. We have the following application of the minimax principle. (See [ADH, Proposition 1.6]; we give a proof based on Theorem A.1.)

THEOREM A.2. *Let A be a bounded self-adjoint operator, and let $V_2 \geq V_1 \geq 0$ be bounded and relatively compact with respect to A . If for any given n we have $\lambda_n^+(\sqrt{V_1}A\sqrt{V_1}) > 0$, then*

$$(A.123) \quad \lambda_n^+(\sqrt{V_2}A\sqrt{V_2}) \geq \lambda_n^+(\sqrt{V_1}A\sqrt{V_1}).$$

Similarly, if for any given n we have $\lambda_n^-(\sqrt{V_1}A\sqrt{V_1}) < 0$, then

$$(A.124) \quad \lambda_n^-(\sqrt{V_2}A\sqrt{V_2}) \leq \lambda_n^-(\sqrt{V_1}A\sqrt{V_1}).$$

Proof. Let us first assume that 0 is not an eigenvalue of V_1 , so $V_1^{-1} \geq V_2^{-1} \geq 0$ are self-adjoint operators.

Now suppose that $\lambda_n^-(\sqrt{V_1}A\sqrt{V_1}) < 0$ and set $\mathcal{S}_- = \{\psi : \langle \psi, A\psi \rangle \leq 0\}$. Using Theorem A.1 we may write

$$\begin{aligned}
 \lambda_n^-(\sqrt{V_1}A\sqrt{V_1}) &= \inf_{L: \dim L=n} \left[\sup_{\psi \in L} \frac{\langle \psi, \sqrt{V_1}A\sqrt{V_1}\psi \rangle}{\|\psi\|^2} \right] \\
 &= \inf_{L \subset \mathcal{D}(V_1^{-1}): \dim L=n} \left[\sup_{\psi \in L} \frac{\langle \psi, A\psi \rangle}{\langle \psi, V_1^{-1}\psi \rangle} \right] \\
 \text{(A.125)} \quad &= \inf_{L \subset \mathcal{D}(V_1^{-1}): \dim L=n, L \subset \mathcal{S}_-} \left[\sup_{\psi \in L} \frac{\langle \psi, A\psi \rangle}{\langle \psi, V_1^{-1}\psi \rangle} \right].
 \end{aligned}$$

In particular, there exists an n -dimensional subspace $L_n \subset \mathcal{D}(V_1^{-1})$ such that $L_n \subset \mathcal{S}_-$. Using Theorem A.1 again we get

$$\text{(A.126)} \quad \lambda_n^-(\sqrt{V_2}A\sqrt{V_2}) = \inf_{L \subset \mathcal{D}(V_2^{-1}): \dim L=n,} \left[\sup_{\psi \in L} \frac{\langle \psi, A\psi \rangle}{\langle \psi, V_2^{-1}\psi \rangle} \right].$$

Since for $L = L_n$ clearly

$$\sup_{\psi \in L_n} \frac{\langle \psi, A\psi \rangle}{\langle \psi, V_2^{-1}\psi \rangle} < 0,$$

we have $\lambda_n^-(\sqrt{V_2}A\sqrt{V_2}) < 0$, which together with (A.126) implies

$$\text{(A.127)} \quad \lambda_n^-(\sqrt{V_2}A\sqrt{V_2}) = \inf_{L \subset \mathcal{D}(V_2^{-1}): \dim L=n, L \subset \mathcal{S}_-} \left[\sup_{\psi \in L} \frac{\langle \psi, A\psi \rangle}{\langle \psi, V_2^{-1}\psi \rangle} \right].$$

Taking now into account the fact that for any $L \subset \mathcal{S}_-$ and $\psi \in L$, we have $\langle \psi, A\psi \rangle \leq 0$, and the inequality $V_1^{-1} \geq V_2^{-1}$, we deduce from (A.125) and (A.127) the following inequality:

$$\begin{aligned}
 \lambda_n^-(\sqrt{V_2}A\sqrt{V_2}) & \\
 \text{(A.128)} \quad &= \inf_{L \subset \mathcal{D}(V_2^{-1}): \dim L=n, L \subset \mathcal{S}_-} \left[\sup_{\psi \in L} \frac{\langle \psi, A\psi \rangle}{\langle \psi, V_2^{-1}\psi \rangle} \right] \\
 &\leq \inf_{L \subset \mathcal{D}(V_1^{-1}): \dim L=n, L \subset \mathcal{S}_-} \left[\sup_{\psi \in L} \frac{\langle \psi, A\psi \rangle}{\langle \psi, V_1^{-1}\psi \rangle} \right] = \lambda_n^-(\sqrt{V_1}A\sqrt{V_1}),
 \end{aligned}$$

which implies the inequality (A.124) under the additional assumption that 0 is not an eigenvalue of V_1 . To get rid of it let us take any positive compact operator V_0 , with 0 not an eigenvalue of V_0 , and $\delta > 0$. Note that $\lambda_n^-(\sqrt{V}A\sqrt{V})$ is a continuous function of V in the operator norm; hence, if $\lambda_n^-(\sqrt{V_1}A\sqrt{V_1}) < 0$, for sufficiently small $\delta > 0$, we must have $\lambda_n^-(\sqrt{V_1 + \delta V_0}A\sqrt{V_1 + \delta V_0}) < 0$, so it follows from (A.128) that

$$\text{(A.129)} \quad \lambda_n^-(\sqrt{V_2 + \delta V_0}A\sqrt{V_2 + \delta V_0}) \leq \lambda_n^-(\sqrt{V_1 + \delta V_0}A\sqrt{V_1 + \delta V_0}).$$

Sending δ to zero in (A.129), we arrive at (A.124) without additional conditions.

The inequality (A.123) is proved in a similar way. \square

Appendix B. An “a priori” estimate for the exponential decay of resolvents. The following result is proven in [FK3, Lemmas 12 and 13] and [FK5, Lemmas 15 and 16]. We use ∇^\sharp to denote ∇ if $W = A$ and ∇^\times if $W = M$. Recall χ_x denotes the characteristic function of a cube of side 1 centered at x .

PROPOSITION B.1. *Let $\varepsilon(x)$ be as in (4). Then there exists a finite constant α_d , depending only on the dimension d , such that*

$$(B.130) \quad \|\chi_x \tilde{R}(-1)\chi_y\| \leq \alpha_d e^{-\beta|x-y|}$$

and

$$(B.131) \quad \left\| \chi_x \nabla^\sharp \tilde{R}(-1)\chi_y \right\| \leq \alpha_d \sqrt{\varepsilon_+} \left(\sqrt{\varepsilon_-} + \frac{1}{\sqrt{\varepsilon_-}} \right) e^{-\beta|x-y|},$$

for all $x, y \in \mathbb{R}^d$, where

$$(B.132) \quad \beta = \frac{1}{4 \lceil \varepsilon_-^{-1} + 2 \rceil}.$$

Appendix C. Some operator estimates. Let χ_x be the characteristic function of the unit cube centered at x . For any $\varphi \in L^2(\mathbb{R}^d; \mathbb{C}^\nu)$, we consider the decomposition

$$(C.133) \quad \varphi = \sum_{m \in \mathbb{Z}^d} \varphi_m, \quad \varphi_m = \chi_m \varphi.$$

If T is a bounded operator in $L^2(\mathbb{R}^d; \mathbb{C}^\nu)$, we will consider the following decomposition of T associated with (C.133):

$$(C.134) \quad T = \sum_{n, m \in \mathbb{Z}^d} T_{nm}, \quad T_{nm} = \chi_n T \chi_m.$$

It is convenient to introduce the following normed space of operators:

$$(C.135) \quad \mathcal{F} = \left\{ T; \|T\|_{\mathcal{F}} \equiv \left(\sum_{n, m \in \mathbb{Z}^d} \|T_{nm}\|^2 \right)^{1/2} < \infty \right\}.$$

LEMMA C.1. *\mathcal{F} is a Banach space. Moreover, for $T, S \in \mathcal{F}$ we have*

$$(C.136) \quad \|T\| \leq \|T\|_{\mathcal{F}},$$

$$(C.137) \quad \|ST\|_{\mathcal{F}} \leq \|S\|_{\mathcal{F}} \|T\|_{\mathcal{F}},$$

$$(C.138) \quad \|T\|_{\mathcal{F}} = \|T^*\|_{\mathcal{F}},$$

and

$$(C.139) \quad T^*T \leq \|T\|_{\mathcal{F}}^2 I.$$

Proof. It is routine to verify that \mathcal{F} is a Banach space.

The inequality (C.136) follows from

$$\begin{aligned}
 \text{(C.140)} \quad \|T\varphi\|^2 &= \sum_{n \in \mathbb{Z}^d} \left\| \sum_{m \in \mathbb{Z}^d} T_{nm} \varphi_m \right\|^2 \\
 &\leq \sum_{n \in \mathbb{Z}^d} \left(\sum_{m \in \mathbb{Z}^d} \|T_{nm}\|^2 \sum_{m \in \mathbb{Z}^d} \|\varphi_m\|^2 \right) = \|T\|_{\mathcal{F}}^2 \|\varphi\|^2.
 \end{aligned}$$

To prove (C.137), note

$$\begin{aligned}
 \text{(C.141)} \quad \|ST\|_{\mathcal{F}}^2 &= \sum_{n,m \in \mathbb{Z}^d} \|(ST)_{nm}\|^2 \\
 \text{(C.142)} \quad &= \sum_{n,m \in \mathbb{Z}^d} \left\| \sum_{u \in \mathbb{Z}^d} S_{nu} T_{um} \right\|^2 \leq \sum_{n,m \in \mathbb{Z}^d} \left(\sum_{u \in \mathbb{Z}^d} \|S_{nu}\| \|T_{um}\| \right)^2 \\
 \text{(C.143)} \quad &\leq \sum_{n,m \in \mathbb{Z}^d} \left(\sum_{u \in \mathbb{Z}^d} \|S_{nu}\|^2 \right) \left(\sum_{u \in \mathbb{Z}^d} \|T_{um}\|^2 \right) = \|S\|_{\mathcal{F}}^2 \|T\|_{\mathcal{F}}^2.
 \end{aligned}$$

The equality (C.138) follows from the definition of $\|T\|_{\mathcal{F}}$. The operator inequality (C.139) follows from $T^*T \leq \|T\|^2 I$ and (C.136). \square

The following is an immediate consequence of Lemma C.1.

COROLLARY C.2. *Let Γ be the positive self-adjoint operator on $L^2(\mathbb{R}^d; \mathbb{C}^\nu)$, given by multiplication by the function*

$$\text{(C.144)} \quad \gamma(x) = \sum_{m \in \mathbb{Z}^d} \gamma_m \chi_m(x),$$

where $\{\gamma_m; m \in \mathbb{Z}^d\}$ is a given sequence of strictly positive numbers, and let T be a bounded operator in $L^2(\mathbb{R}^d; \mathbb{C}^\nu)$. Then if $T\Gamma \in \mathcal{F}$, i.e.

$$\text{(C.145)} \quad \|T\Gamma\|_{\mathcal{F}}^2 = \sum_{n,m \in \mathbb{Z}^d} \|T_{nm}\|^2 \gamma_m^2 < \infty,$$

we have the following operator inequality:

$$\text{(C.146)} \quad T^*T \leq \|T\Gamma\|_{\mathcal{F}}^2 \Gamma^{-2}.$$

Proof. We have

$$\text{(C.147)} \quad T^*T = \Gamma^{-1} \Gamma T^* T \Gamma^{-1} \leq \|\Gamma T^* T \Gamma\| \Gamma^{-2}$$

$$\text{(C.148)} \quad = \|T\Gamma\|_{\mathcal{F}}^2 \Gamma^{-2} \leq \|T\Gamma\|_{\mathcal{F}}^2 \Gamma^{-2}. \quad \square$$

Appendix D. An estimate on traces. We use the following lemma.

LEMMA D.1. *Let R be a bounded self-adjoint operator, and let P and Q be two orthogonal projections. Then*

$$\text{(D.149)} \quad \text{Tr}(P R Q R P) \leq 4 \left\{ \text{Tr} \left[(P |R| P)^2 \right] \right\}^{1/2} \left\{ \text{Tr} \left[(Q |R| Q)^2 \right] \right\}^{1/2}.$$

Proof. We write

$$(D.150) \quad R = R_+ - R_-, \quad \text{with } R_{\pm} \geq 0, \quad R_+ R_- = R_- R_+ = 0, \quad \text{so } |R| = R_+ + R_-.$$

Thus

$$(D.151) \quad \begin{aligned} \text{Tr}(PRQRP) &= \|PRQ\|_2^2 \\ &\leq 2(\|PR_+Q\|_2^2 + \|PR_-Q\|_2^2). \end{aligned}$$

Without loss of generality, we may assume that $P|R|P$ and $Q|R|Q$ are Hilbert–Schmidt operators; it follows that $PR_{\pm}P$ and $QR_{\pm}Q$ are also Hilbert–Schmidt, so $R_{\pm}^{1/2}P$, $R_{\pm}^{1/2}Q \in \mathcal{T}_4$. It follows that

$$(D.152) \quad \begin{aligned} \|PR_{\pm}Q\|_2^2 &= \text{Tr}(PR_{\pm}QR_{\pm}P) = \text{Tr}\left(R_{\pm}^{1/2}PR_{\pm}QR_{\pm}^{1/2}\right) \\ &\leq \left\|R_{\pm}^{1/2}PR_{\pm}^{1/2}\right\|_2 \left\|R_{\pm}^{1/2}QR_{\pm}^{1/2}\right\|_2 = \|PR_{\pm}P\|_2 \|QR_{\pm}Q\|_2. \end{aligned}$$

Furthermore,

$$(D.153) \quad \begin{aligned} \|PR_{\pm}P\|_2^2 &= \text{Tr}(PR_{\pm}PR_{\pm}P) = \text{Tr}\left(R_{\pm}^{1/2}PR_{\pm}PR_{\pm}^{1/2}\right) \\ &\leq \text{Tr}\left(R_{\pm}^{1/2}P(R_+ + R_-)PR_{\pm}^{1/2}\right) \\ &= \text{Tr}\left[(R_+ + R_-)^{1/2}PR_{\pm}P(R_+ + R_-)^{1/2}\right] \\ &\leq \text{Tr}\left[(R_+ + R_-)^{1/2}P(R_+ + R_-)P(R_+ + R_-)^{1/2}\right] \\ &= \text{Tr}\left[P(R_+ + R_-)P(R_+ + R_-)P\right] = \text{Tr}\left[(P|R|P)^2\right] \end{aligned}$$

with an analogous estimate for $\|QR_{\pm}Q\|_2^2$. The estimate (D.149) now follows from (D.151), (D.152), and (D.153). \square
