

HOMEWORK 10  
HDP KNU+ FALL 2022

---

As in the previous homework sets,  $C, C_1, C_2, \dots$  and  $c, c_1, c_2, \dots$  denote positive absolute constants of your choice.

Hints are in the back of this homework set.

---

In the following problem we show that whenever two unit vectors  $u, v \in \mathbb{R}^d$  are close to each other, then so are  $P_u = uu^\top$  and  $P_v = vv^\top$ , which are the orthogonal projections onto the lines spanned by these two vectors. We will also prove the converse: if the projections  $P_u$  and  $P_v$  are close, then the vectors must be close up to a sign, i.e.  $u \approx \pm v$ . From this we derive a useful version of Davis-Kahan perturbation theorem for the top eigenvectors.

PROBLEM 1 (PERTURBATION OF EIGENVECTORS)

(a) Let  $x$  and  $y$  be arbitrary vectors in  $\mathbb{R}^d$ . Compute the operator and Frobenius norms of the matrix  $xy^\top$ . (Show your work!)

(b) Let  $u$  and  $v$  be unit vectors in  $\mathbb{R}^d$ . Prove that there exists a sign  $s \in \{-1, 1\}$  such that

$$\frac{1}{2}\|u - sv\|_2 \leq \|uu^\top - vv^\top\| \leq 2\|u - v\|_2,$$

where the norm in the middle is the operator norm.

(c) Deduce the following version of a Davis-Kahan theorem (see Lecture 24, p.3 for a general statement). Let  $A$  and  $B$  be  $d \times d$  symmetric matrices. Then there exist a sign  $s \in \{-1, 1\}$  such that

$$\|v_1(A) - sv_1(B)\|_2 \leq \frac{\|A - B\|}{\lambda_1(A) - \lambda_2(A)}$$

where  $\lambda_k(A)$  denote the eigenvalues of  $A$  in the non-increasing order, and  $v_k(A)$  denote the corresponding unit eigenvectors, and similarly for  $B$ .

---

Consider a probability distribution in  $\mathbb{R}^d$  with mean zero and covariance matrix

$$\Sigma = I + \beta uu^\top \tag{1}$$

where  $\beta > 0$  is a fixed number and  $u \in \mathbb{R}^d$  is a fixed unit vector. This is a *spike model*, a basic mathematical model of data with structure. The data sampled from this distribution looks have variance 1 in all directions except one: in the direction of  $u$  the variance is larger, making a “spike”. The direction of  $u$  is interpreted as a “signal” which may contain some information about the data, while the other directions are noise. The magnitude of  $\beta$  measures the strength of the spike, known as the signal-to-noise ratio (SNR).

In this problem, we will accurately estimate the “signal”  $u$  from a sample of  $n = O(d)$  points  $X_1, \dots, X_n$ . All we have to do is compute  $v_1(\Sigma_n)$ , the eigenvector corresponding to the largest eigenvalue of the sample covariance matrix  $\Sigma_n = \frac{1}{n} \sum_{i=1}^n X_i X_i^\top$ . Obviously,  $u$  can only be recovered up to a sign, and we will show that  $u \approx \pm v_1(\Sigma_n)$  for some choice of the sign.

### PROBLEM 2 (LEARNING A SPIKE MODEL)

(a) Check that the two largest eigenvalues of the spike covariance matrix  $\Sigma$  in (1) are  $\lambda_1(\Sigma) = 1 + \beta$  and  $\lambda_2(\Sigma) = 1$ . Check that the top eigenvector is  $v_1(\Sigma) = u$ .

(b) Assume that  $X_1, \dots, X_n$  are i.i.d. subgaussian random vectors in  $\mathbb{R}^d$  with mean zero, covariance matrix  $\Sigma$  as in (1), and with  $\|X_i\|_{\psi_2} \leq 10$ . Let  $v = v_1(\Sigma_n)$  be the top eigenvector of the sample covariance matrix. Show that if  $n \geq C_2 d / \beta^2$ , then

$$\min_{s \in \{-1, 1\}} \|u - sv\|_2 \leq 0.01$$

with probability at least  $1 - 2e^{-d}$ .

In Lecture 28, November 7, we developed *matrix calculus* that allows us to work with  $d \times d$  symmetric matrices as if they were numbers. In particular, we introduced the (partial) semidefinite order<sup>1</sup> and defined functions of matrices.<sup>2</sup>

Most facts about numbers transfer to matrices, but some do not. Part (a) of this problem gives a matrix version of the following fact about scalars:

$$|x| \leq t \iff -t \leq x \leq t \quad \text{for } x \in \mathbb{R}.$$

Part (d) unexpectedly shows that the scalar fact

$$f : \mathbb{R} \rightarrow \mathbb{R} \text{ increasing function, } x \leq y \implies f(x) \leq f(y)$$

does not generalize to matrices.

### PROBLEM 3 (MATRIX CALCULUS)

In this problem,  $X$  and  $Y$  denote  $d \times d$  symmetric real matrices.

(a) Prove that  $\|X\| \leq t$  if and only if  $-tI \preceq X \preceq tI$ .

(b) Let  $f, g : \mathbb{R} \rightarrow \mathbb{R}$  be two functions. Prove that  $f(x) \leq g(x)$  for all  $x \in \mathbb{R}$  satisfying  $|x| \leq K$ , then  $f(X) \preceq g(X)$  for all  $X$  satisfying  $\|X\| \leq K$ .

(c) Let  $f : \mathbb{R} \rightarrow \mathbb{R}$  be an increasing function and  $X, Y$  be commuting matrices. Prove that  $X \preceq Y$  implies  $f(X) \preceq f(Y)$ .

(d) Show by example that property (d) may fail for non-commuting matrices.

<sup>1</sup>To recall this definition, we write  $X \succeq 0$  if  $X$  is a symmetric positive semidefinite matrix. We say that  $X \succeq Y$ , or equivalently,  $Y \preceq X$ , if  $X - Y \succeq 0$ .

<sup>2</sup>To recall this definition, let  $f : \mathbb{R} \rightarrow \mathbb{R}$  and let  $A = \sum_{i=1}^d \lambda_i u_i u_i^\top$  be a spectral decomposition of  $A$ . We define  $f(A) = \sum_{i=1}^d f(\lambda_i) u_i u_i^\top$ .

## HINTS

## HINT FOR PROBLEM 1.

(a) Both norms equal  $\|x\|_2 \|y\|_2$ .

(b) The second inequality is simpler. To prove it, add and subtract the cross term  $uv^\top$  and use triangle inequality; this reduces the problem to computing the norms of  $u(u-v)^\top$  and  $(u-v)v^\top$ ; use the result of part (a) and the assumption that  $\|u\|_2 = \|v\|_2 = 1$ .

To prove the first inequality in (b), assume without loss of generality that  $\langle u, v \rangle \geq 0$  (otherwise replace  $u$  by  $-u$ ), let  $R = uu^\top - vv^\top$  and  $\varepsilon = \|R\|$ . Then  $|u^\top Ru| \leq \varepsilon$  (why?); deduce from this that  $|1 - \langle u, v \rangle| \leq \varepsilon$  and thus  $\|u - u\langle u, v \rangle\|_2 \leq \varepsilon$ . Moreover,  $\|Rv\|_2 \leq \varepsilon$  (why?); this means that  $\|u\langle u, v \rangle - v\|_2 \leq \varepsilon$ . Add the two bounds using triangle inequality to conclude that  $\|u - v\|_2 \leq \varepsilon$ .

(c) Apply the general Davis-Kahan theorem for  $k = 1$ ; then use the first inequality in part (b) to pass from the projections to the eigenvectors.

## HINT FOR PROBLEM 2.

(b) Use the covariance estimation result from HW 9, Problem 3(a). Combine it with the results of Problem 1(c) and 2(a) of the current homework.

## HINT FOR PROBLEM 3.

(a) Recall that the operator norm of  $X$  can be computed as the maximum of the quadratic form  $u^\top Xu$  over all unit vectors  $u \in \mathbb{R}^d$ .

(c) Commuting symmetric matrices are simultaneously diagonalizable by an orthogonal matrix, so we can write their spectral representations with the same eigenvectors.

(d) Find  $2 \times 2$  matrices such that  $0 \preceq X \preceq Y$  but  $X^2 \not\preceq Y^2$ .
